React Rendering & useEffect Notes

Key Terms

Term	Simple meaning
Render	React figures out what the UI should be
Mount	The UI is added to the webpage for the first time
Re-render	React figures out the UI again after something changes

The DOM

DOM stands for Document Object Model.

In simple terms: the DOM is the browser's representation of your webpage as a tree of elements.

Loading State

Your app is waiting for something to finish, such as fetching data or checking authentication.

useEffect Dependency Arrays

The behavior of **useEffect** changes depending on what you pass as its second argument (the dependency array).

1. No dependency array → after every render

```
useEffect(() => {
    // run this
});
```

Meaning: "Every time this component renders, run this effect."

2. Empty dependency array → after mounting

```
useEffect(() => {
    // run this
}, []);
```

Meaning: "When this component first mounts, run this effect."

3. Dependency array with values → when those values change

```
useEffect(() => {
    // run this
}, [count]);
```

Meaning: "Run this when `count` changes."

It also runs when the component first mounts.

With multiple dependencies:

```
useEffect(() => {
    // run this
}, [count, color]);
```

Meaning: "Run this when `count` or `color` changes."
